```
import numpy as np
import pandas as pd
import datetime
```

Feature Engineering

 Feature Engineering is the process of transforming data to increase the predictive performance of machine learning models

Data normalization:

 Data Normalization could also be a typical practice in machine learning which consists of transforming numeric columns to a standard scale.

```
data = {
  'col1': [1,2,3,4,5],
  'col2': [8,7,3,6,4],
  'col3': [12000, 23000, 45000, 34000, 21000]
df = pd.DataFrame(data)
print(df)
        col1 col2
                   col3
                8 12000
                7 23000
                3 45000
    2
          3
                6 34000
                4 21000
import matplotlib.pyplot as plt
df.plot(kind = 'bar')
```

import matplotlib.pyplot as plt
df.plot(kind = 'bar')
When plotting the graph, we can see that,
col3 has dominated the graph and we cannot observe the others.

```
# So, we can scale all column data in smaller ranges for column in df.columns:
    df[column] = df[column] / df[column].abs().max()

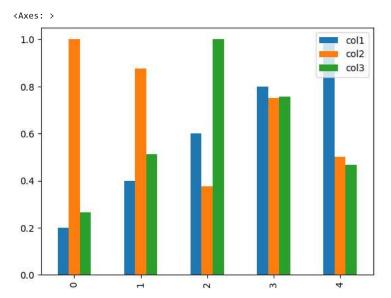

print(df)

# Now, we can see all the col values are closer to each other

    col1    col2    col3
    0    0.2    1.000    0.266667
    1    0.4    0.875    0.511111
    2    0.6    0.375    1.000000
    3    0.8    0.750    0.755556
```

1.0 0.500 0.466667

```
import matplotlib.pyplot as plt
df.plot(kind = 'bar')
# Now, we can observe features from the graph.
```

Scaling:

- In cases where all the columns have a significant difference in their scales, are needed to be modified in such a way that all those values fall into the same scale. This process is called **Scaling**.
- There are two most common techniques of how to scale columns of Pandas dataframe -
 - 1. Min-Max Normalization
 - 2. Standardization.

```
df = pd.read_csv('IRIS.csv')
print(df.head())
        sepal_length sepal_width petal_length petal_width
    a
                5.1
                             3.5
                                           1.4
                                                        0.2 Iris-setosa
    1
                4.9
                             3.0
                                           1.4
                                                        0.2 Iris-setosa
     2
                4.7
                             3.2
                                           1.3
                                                        0.2 Iris-setosa
                 4.6
                             3.1
                                           1.5
                                                        0.2
                                                             Iris-setosa
     4
                                                        0.2 Iris-setosa
```

1. min-max Normalization:

- Here, all the values are scaled in between the range of [0,1] where 0 is the minimum value and 1 is the maximum value.
- The formula for Min-Max Normalization is -

 $x_norm = (x - x_min) / (x_max - x_min)$

```
RangeIndex: 150 entries, 0 to 149
Data columns (total 5 columns):

# Column Non-Null Count Dtype
------
0 sepal_length 150 non-null float64
1 sepal_width 150 non-null float64
2 petal_length 150 non-null float64
3 petal_width 150 non-null float64
4 species 150 non-null float64
4 species 150 non-null object
dtypes: float64(4), object(1)
memory usage: 6.0+ KB
None
```

```
new_df = df.drop('species', axis=1) # Have to use axis=1, for column
```

```
# Now, perform scaling on each value of each column
df_norm = ((new_df-new_df.min()) / (new_df.max()-new_df.min()))
# Now, merge the normalized df with the dropped species col
final_df = pd.concat((df_norm, df.species), axis=1)
print(final_df)
          sepal_length sepal_width petal_length petal_width
                                                                       species

     [150 rows x 5 columns]
# Using MinMaxScaler from sklearn
from sklearn.preprocessing import MinMaxScaler
import pandas as pd
# Drop species col, having str data
new_df = df.drop('species', axis=1)
scaler = MinMaxScaler()
df_scaled = scaler.fit_transform(new_df.to_numpy())
df_scaled = pd.DataFrame(df_scaled, columns=[
  'sepal_length', 'sepal_width', 'petal_length', 'petal_width'])
print("Scaled Dataset Using MinMaxScaler")
df_scaled.head()
     Scaled Dataset Using MinMaxScaler
                                                                      th
```

	sepal_length	sepal_width	petal_length	petal_width	1
0	0.222222	0.625000	0.067797	0.041667	
1	0.166667	0.416667	0.067797	0.041667	
2	0.111111	0.500000	0.050847	0.041667	
3	0.083333	0.458333	0.084746	0.041667	
4	0.194444	0.666667	0.067797	0.041667	

2. Standardization:

- · Standardization doesn't have any fixed minimum or maximum value.
- · Here, the values of all the columns are scaled in such a way that they all have a mean equal to 0 and standard deviation equal to 1.
- This scaling technique works well with outliers.
- · Thus, this technique is preferred if outliers are present in the dataset.

```
import pandas as pd
from sklearn.preprocessing import StandardScaler

# Drop species col, having str data
new_df = df.drop('species', axis=1)

std_scaler = StandardScaler()

df_scaled = std_scaler.fit_transform(new_df.to_numpy())

df_scaled = pd.DataFrame(df_scaled, columns=[
'sepal_length','sepal_width','petal_length','petal_width'])

print("Scaled Dataset Using StandardScaler")

df_scaled.head()
```

Scaled Dataset Using StandardScaler sepal_length sepal_width petal_length petal_width d. -0.900681 1.032057 -1.341272 -1.312977 1 -1.143017 -0.124958 -1.341272 -1.312977 -1.385353 0.337848 -1.398138 -1.312977

Time Series Analysis and Resampling

Pandas provide a different set of tools using which we can perform all the necessary tasks on date-time data.

Working with datetime data:

```
#1: Create a dates dataframe
# Create dates dataframe with frequency
data = pd.date_range('1/1/2011', periods = 15, freq ='M')
data
    dtype='datetime64[ns]', freq='M')
# 2: Current date and time
# x = pd.datetime.now()
# x.date, x.month, x.year
stamp = pd.Timestamp(datetime.datetime(2023, 8, 4))
stamp = pd.Timestamp(datetime.datetime.now())
print(stamp)
result = stamp.today()
print(result)
print(stamp.day_name())
print(stamp.day_of_week)
print(stamp.weekday())
print(stamp.hour)
print(stamp.day)
print(stamp.days_in_month)
print(stamp.date())
print(stamp.dayofyear)
print(stamp.daysinmonth)
print(stamp.minute)
     2023-08-04 14:25:05.287975
     2023-08-04 14:25:05.289076

# Create date and time with dataframe
rng = pd.DataFrame()
rng['date'] = pd.date_range(datetime.datetime.now(), periods = 72, freq ='H')
# Print the dates in dd-mm-yy format
rng[:5]
# Create features for year, month, day, hour, and minute
rng['year'] = rng['date'].dt.year
rng['month'] = rng['date'].dt.month
rng['day'] = rng['date'].dt.day
rng['hour'] = rng['date'].dt.hour
rng['minute'] = rng['date'].dt.minute
rng['second'] = rng['date'].dt.second
```

Print the dates divided into features
rng.head(3)

	date	year	month	day	hour	minute	second	10:	ılı
0	2023-08-04 14:25:09.473671	2023	8	4	14	25	9		
1	2023-08-04 15:25:09.473671	2023	8	4	15	25	9		
2	2023-08-04 16:25:09.473671	2023	8	4	16	25	9		

Resampling and time-based indexing:

Handling time zones and date offsets:

- Dateoffsets are a standard kind of date increment used for a date range in Pandas.
- DateOffsets can be created to move dates forward a given number of valid dates.
- Pandas tseries.offsets.DateOffset is used to create standard kind of date increment used for a date range.
- Syntax:

```
pandas.tseries.offsets.DateOffset(n=1, normalize=False, **kwds)
```

Parameters:

- on: The number of time periods the offset represents.
- o normalize: Whether to round the result of a DateOffset addition down to the previous midnight.
- level: int, str, default None
- **kwds: Temporal parameter that add to or replace the offset value. Parameters that add to the offset (like Timedelta): years, months etc.
- Returns : DateOffsets

```
# Creating Timestamp
ts = pd.Timestamp('2019-10-10 07:15:11')
print(ts)
# Create the DateOffset
do = pd.tseries.offsets.DateOffset(n = 2)
print(do)
# We can now add the DateOffset to any date, to increment the date
new_date = ts + do
print(new_date)
# Thus, the date would move forward by 2 days.
     2019-10-10 07:15:11
     <2 * DateOffsets>
     2019-10-12 07:15:11
# Providing additional arguments to the DateOffset
today = pd.Timestamp(datetime.datetime.now())
# Create new DateOffset
date_off = pd.tseries.offsets.DateOffset(days=10, hours=3, minutes=15)
\mbox{\#} Move the timestamp by 10 days, 3 hrs and 15 mins
future_date = today + date_off
print(today)
print(future_date)
     2023-08-04 14:25:21.270023
     2023-08-14 17:40:21.270023
```

Working with datetime data in pandas:

Datetime features can be divided into two categories:

· The first one: time moments in a period

- · Second: the time passed since a particular period.
- These features can be very useful to understand the patterns in the data.

Divide a given date into features -

- pandas.Series.dt.year returns the year of the date time.
- pandas.Series.dt.month returns the month of the date time.
- · pandas.Series.dt.day returns the day of the date time.
- pandas.Series.dt.hour returns the hour of the date time.
- pandas.Series.dt.minute returns the minute of the date time.

```
#3: Break date and time into separate features
# Create date and time with dataframe
rng = pd.DataFrame()
rng['date'] = pd.date_range(datetime.datetime.now().date(), periods = 72, freq ='H')
# Print the dates in dd-mm-yy format
rng[:5]
# Create features for year, month, day, hour, and minute
rng['year'] = rng['date'].dt.year
rng['month'] = rng['date'].dt.month
rng['day'] = rng['date'].dt.day
rng['hour'] = rng['date'].dt.hour
rng['minute'] = rng['date'].dt.minute
# Print the dates divided into features
rng.head(10)
                                                             1
                                                                   ılı.
                      date year
                                 month
                                        day
                                            hour
                                                   minute
      0 2023-08-04 00:00:00 2023
                                      8
                                                0
                                                        0
```

Resampling time series data (e.g., downsampling and upsampling):

- Pandas dataframe.resample() function is primarily used for time series data.
- A time series is a series of data points indexed (or listed or graphed) in time order.
- It is a Convenience method for frequency conversion and resampling of time series.
- Object must have a datetime-like index (DatetimeIndex, PeriodIndex, or TimedeltaIndex), or pass datetime-like values to the on or level keyword.

• Syntax:

```
DataFrame.resample(rule, how=None, axis=0, fill_method=None, closed=None, label=None, convention='start', kind=None, lof-
```

• Parameters :

- rule: the offset string or object representing target conversion
- \circ axis: int, optional, default 0
- closed : {'right', 'left'}
- o label: {'right', 'left'}
- o convention: For PeriodIndex only, controls whether to use the start or end of rule

- loffset: Adjust the resampled time labels
- **base**: For frequencies that evenly subdivide 1 day, the "origin" of the aggregated intervals. For example, for '5min' frequency, base could range from 0 through 4. Defaults to 0.
- on: For a DataFrame, column to use instead of index for resampling. Column must be datetime-like.
- level: For a MultiIndex, level (name or number) to use for resampling. Level must be datetime-like.
- Resampling generates a unique sampling distribution on the basis of the actual data.
- · Most commonly used time series frequency are -
 - W: weekly frequency
 - M: month end frequency
 - SM: semi-month end frequency (15th and end of month)
 - Q: quarter end frequency

Working with time-based data in pandas (e.g., datetime index):

```
# index_col ="start_date", makes "start_date" column, the index of the data frame
df = pd.read_csv('covid_data.csv', parse_dates =["start_date"], index_col ="start_date")

df['end'] = pd.to_datetime(df.end)
# Printing the dataframe
df
```
